

Chapter 1: Introduction to Pattern Recognition

- ❖ Machine Perception
- ❖ An example
- ❖ Pattern Recognition Systems
- ❖ The Design Cycle
- ❖ Learning and Adaptation
- ❖ Conclusion

All materials used in this course were taken from the textbook "*Pattern Classification*" by Duda et al., John Wiley & Sons, 2001 with the permission of the authors and the publisher

Machine Perception

- ❖ Build a machine that can recognize patterns:
 - ❖ Speech recognition
 - ❖ Fingerprint identification
 - ❖ OCR (Optical Character Recognition)
 - ❖ DNA sequence identification

An Example

“Sorting incoming Fish on a conveyor according to species using optical sensing”

❖ Problem Analysis

- ❖ Set up a camera and take some sample images to extract features
 - ❖ Length
 - ❖ Lightness
 - ❖ Width
 - ❖ Number and shape of fins
 - ❖ Position of the mouth, etc...

This is the set of all suggested features to explore for use in our classifier!

❖ Preprocessing

- ❖ Use a segmentation operation to isolate fishes from one another and from the background
- ❖ Information from a single fish is sent to a feature extractor whose purpose is to reduce the data by measuring certain features
- ❖ The features are passed to a classifier

2

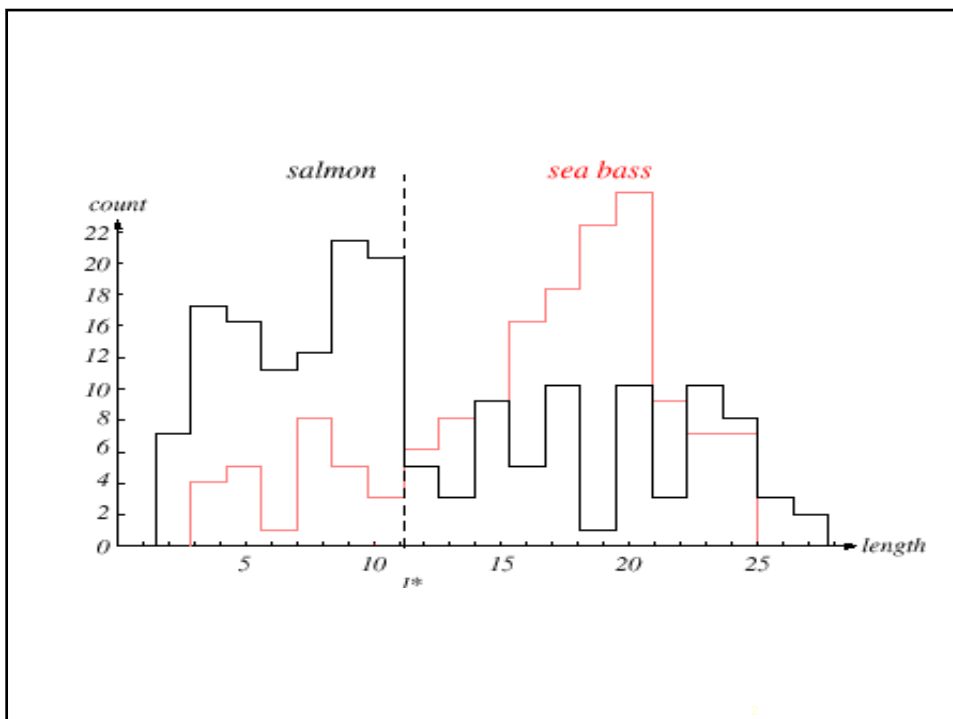

2

❖ Classification

Select the length of the fish as a possible feature for discrimination

2

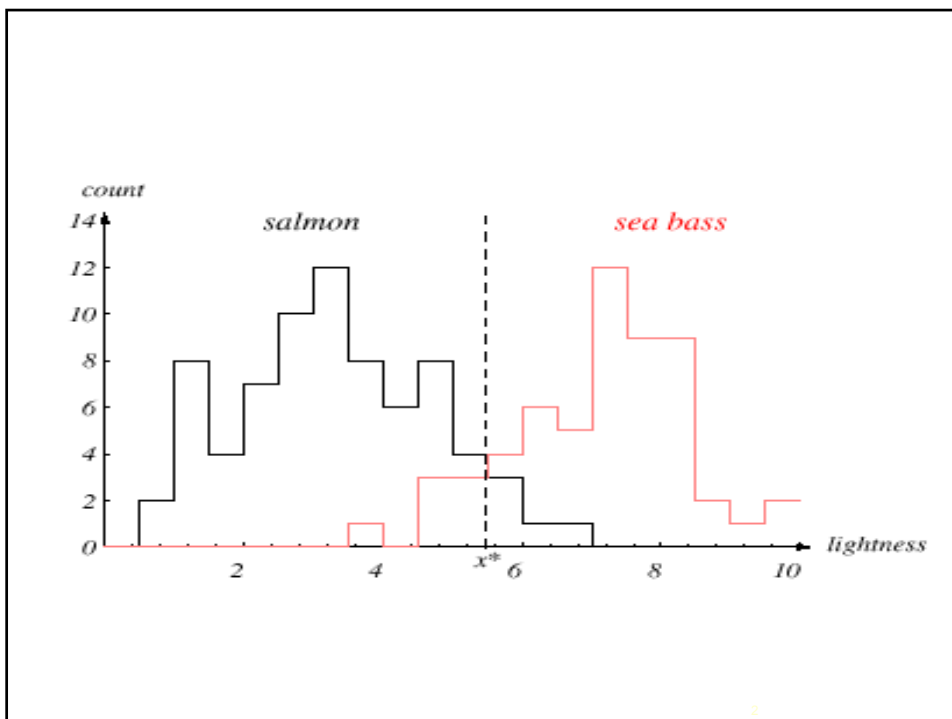

2

The length is a poor feature alone!

Select the lightness as a possible feature.

2

2

- ❖ Threshold decision boundary and cost relationship

- ❖ Move our decision boundary toward smaller values of lightness in order to minimize the cost (reduce the number of sea bass that are classified salmon!)

Task of decision theory

2

- ❖ Adopt the lightness and add the width of the fish

2

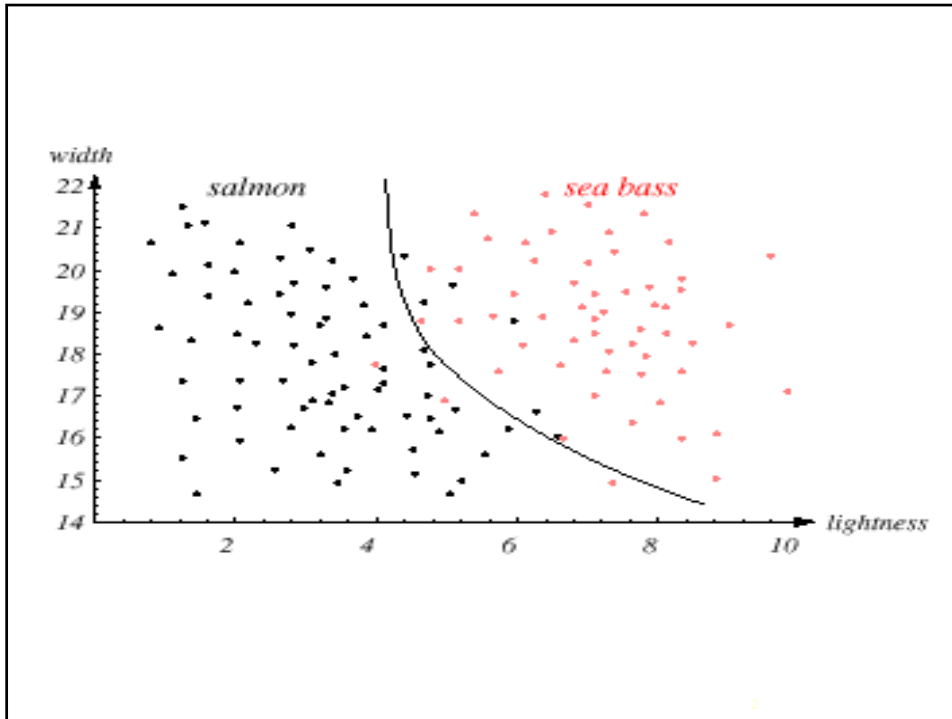

- ❖ We might add other features that are not correlated with the ones we already have. A precaution should be taken not to reduce the performance by adding such “noisy features”
- ❖ Ideally, the best decision boundary should be the one which provides an optimal performance such as in the following figure:

❖ However, our satisfaction is premature because the central aim of designing a classifier is to correctly classify novel input

Issue of generalization!

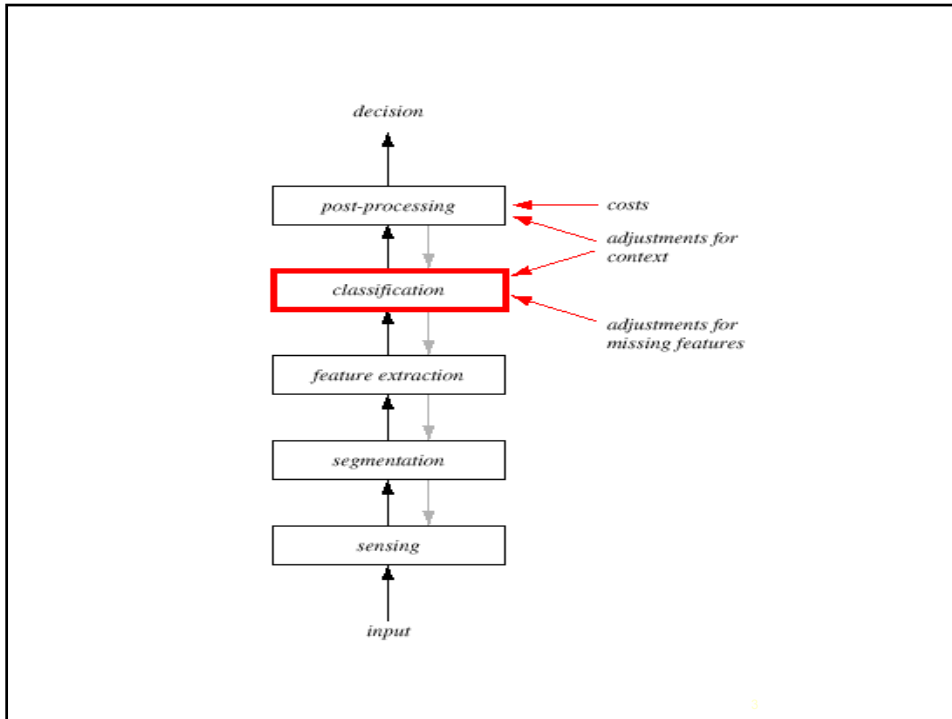

Pattern Recognition Systems

❖ Sensing

- ❖ Use of a transducer (camera or microphone)
- ❖ PR system depends of the bandwidth, the resolution sensitivity distortion of the transducer

❖ Segmentation and grouping

- ❖ Patterns should be well separated and should not overlap

❖ Feature extraction

- ❖ Discriminative features
- ❖ Invariant features with respect to translation, rotation and scale.

❖ Classification

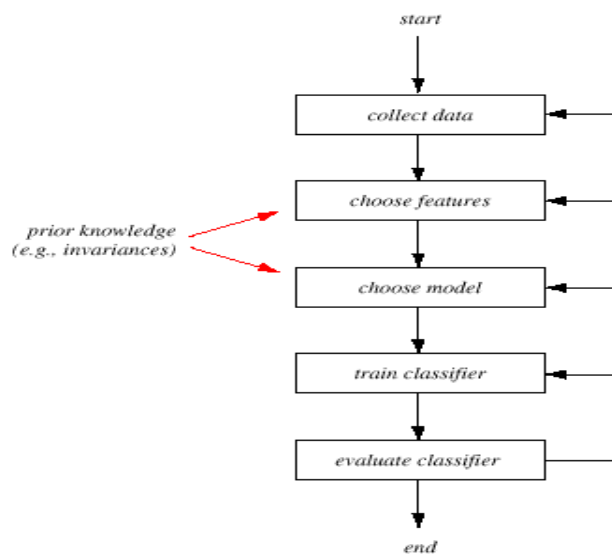

- ❖ Use a feature vector provided by a feature extractor to assign the object to a category

❖ Post Processing

- ❖ Exploit context input dependent information other than from the target pattern itself to improve performance

The Design Cycle

- ❖ Data collection
- ❖ Feature Choice
- ❖ Model Choice
- ❖ Training
- ❖ Evaluation
- ❖ Computational Complexity

❖ Data Collection

How do we know when we have collected an adequately large and representative set of examples for training and testing the system?

❖ Feature Choice

Depends on the characteristics of the problem domain. Simple to extract, invariant to irrelevant transformation insensitive to noise.

❖ Model Choice

Unsatisfied with the performance of our fish classifier and want to jump to another class of model

❖ Training

Use data to determine the classifier. Many different procedures for training classifiers and choosing models

❖ Evaluation

Measure the error rate (or performance and switch from one set of features to another one

❖ Computational Complexity

What is the trade off between computational ease and performance?

(How an algorithm scales as a function of the number of features, patterns or categories?)

Learning and Adaptation

- ❖ Supervised learning
 - ❖ A teacher provides a category label or cost for each pattern in the training set
- ❖ Unsupervised learning
 - ❖ The system forms clusters or “natural groupings” of the input patterns

5

Conclusion

- ❖ Reader seems to be overwhelmed by the number, complexity and magnitude of the sub-problems of Pattern Recognition
- ❖ Many of these sub-problems can indeed be solved
- ❖ Many fascinating unsolved problems still remain

6
